Cellular lineage tracking with time-lapse microscopy

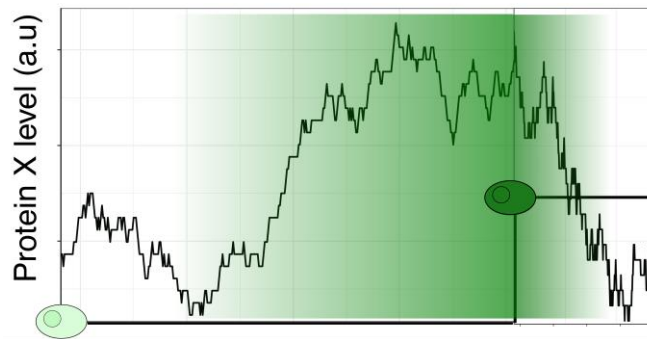

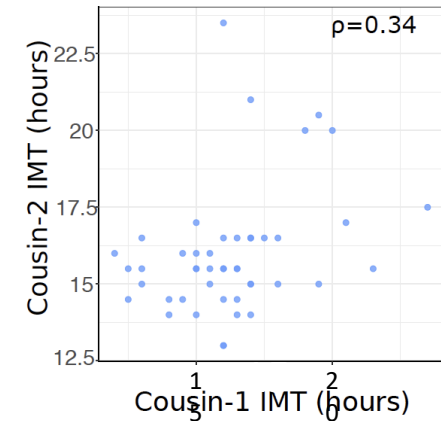

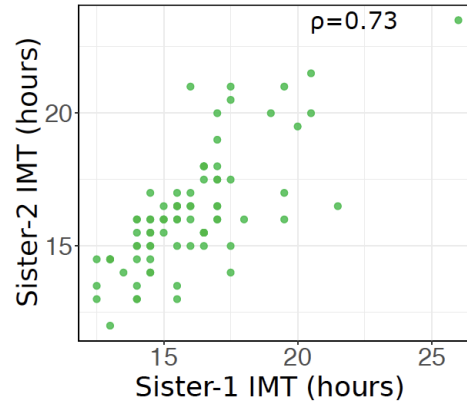

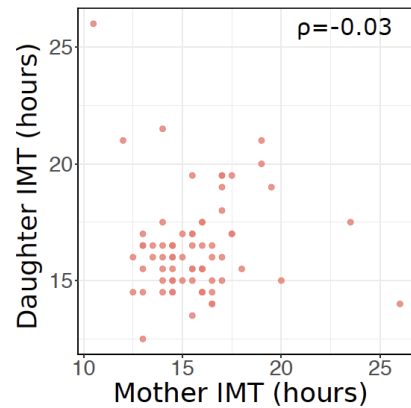

Cell line: HEK293T
Average division time: 24 hours
Duration of movie: 32 hours
Fluorescence: H2B – Cyan Fluorescent Protein

What can we learn from lineage correlations?

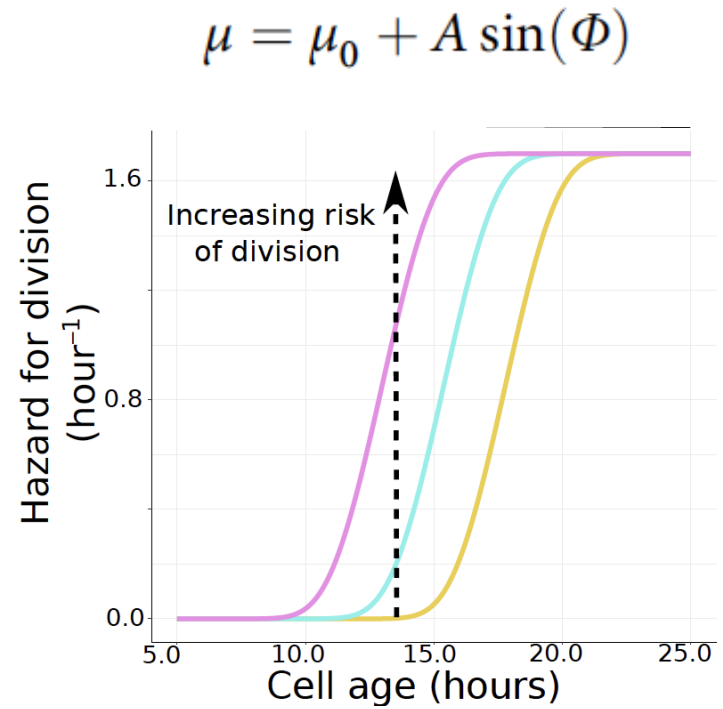

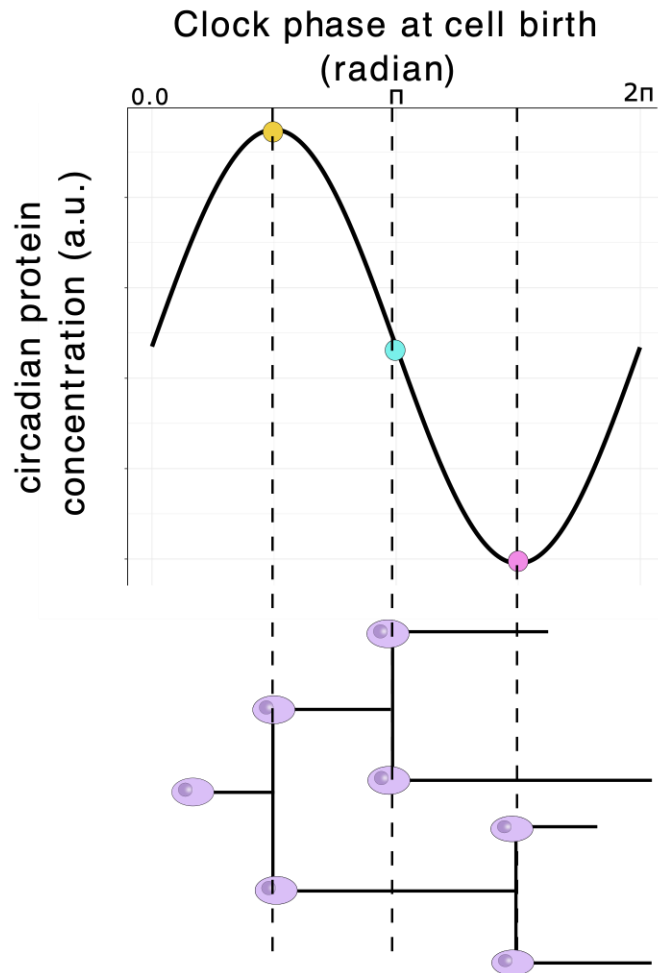

Simple cell cycle models cannot explain lineage correlations

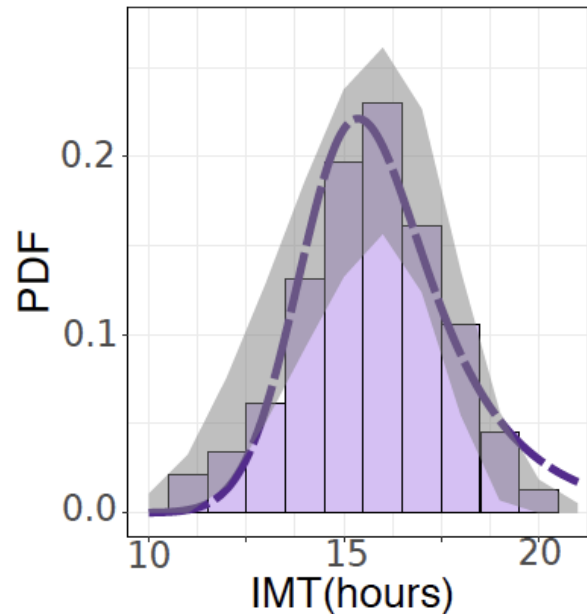

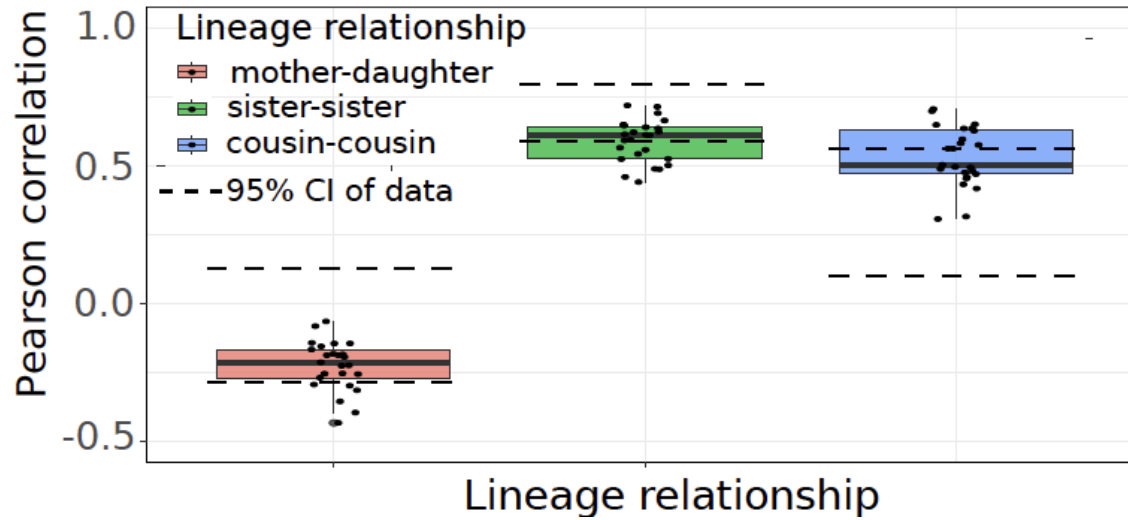

“Cousin-mother inequality” in the HCT116 cell line

A model of circadian-controlled cell fate probability

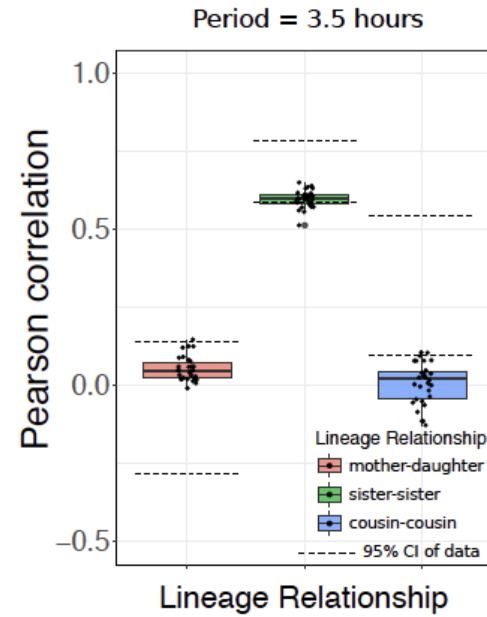

Coupling to circadian rhythm recapitulates correlations and IMT distribution

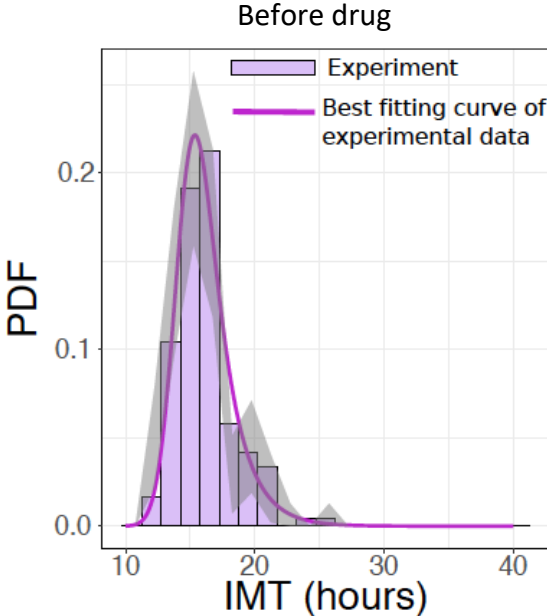

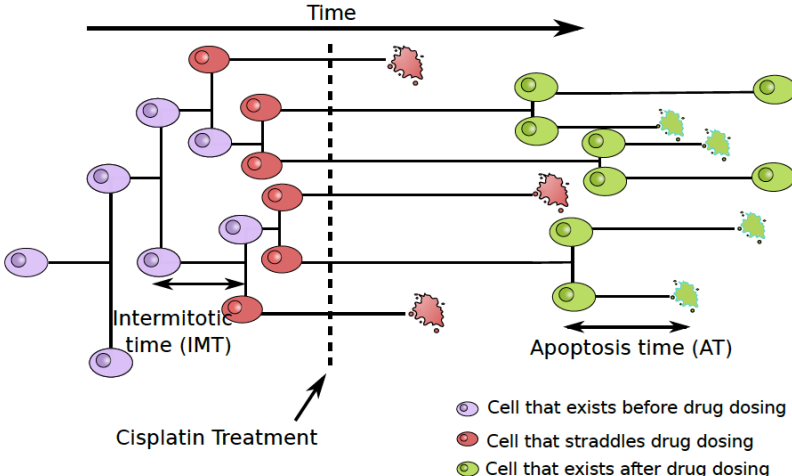

Only 4 free parameters

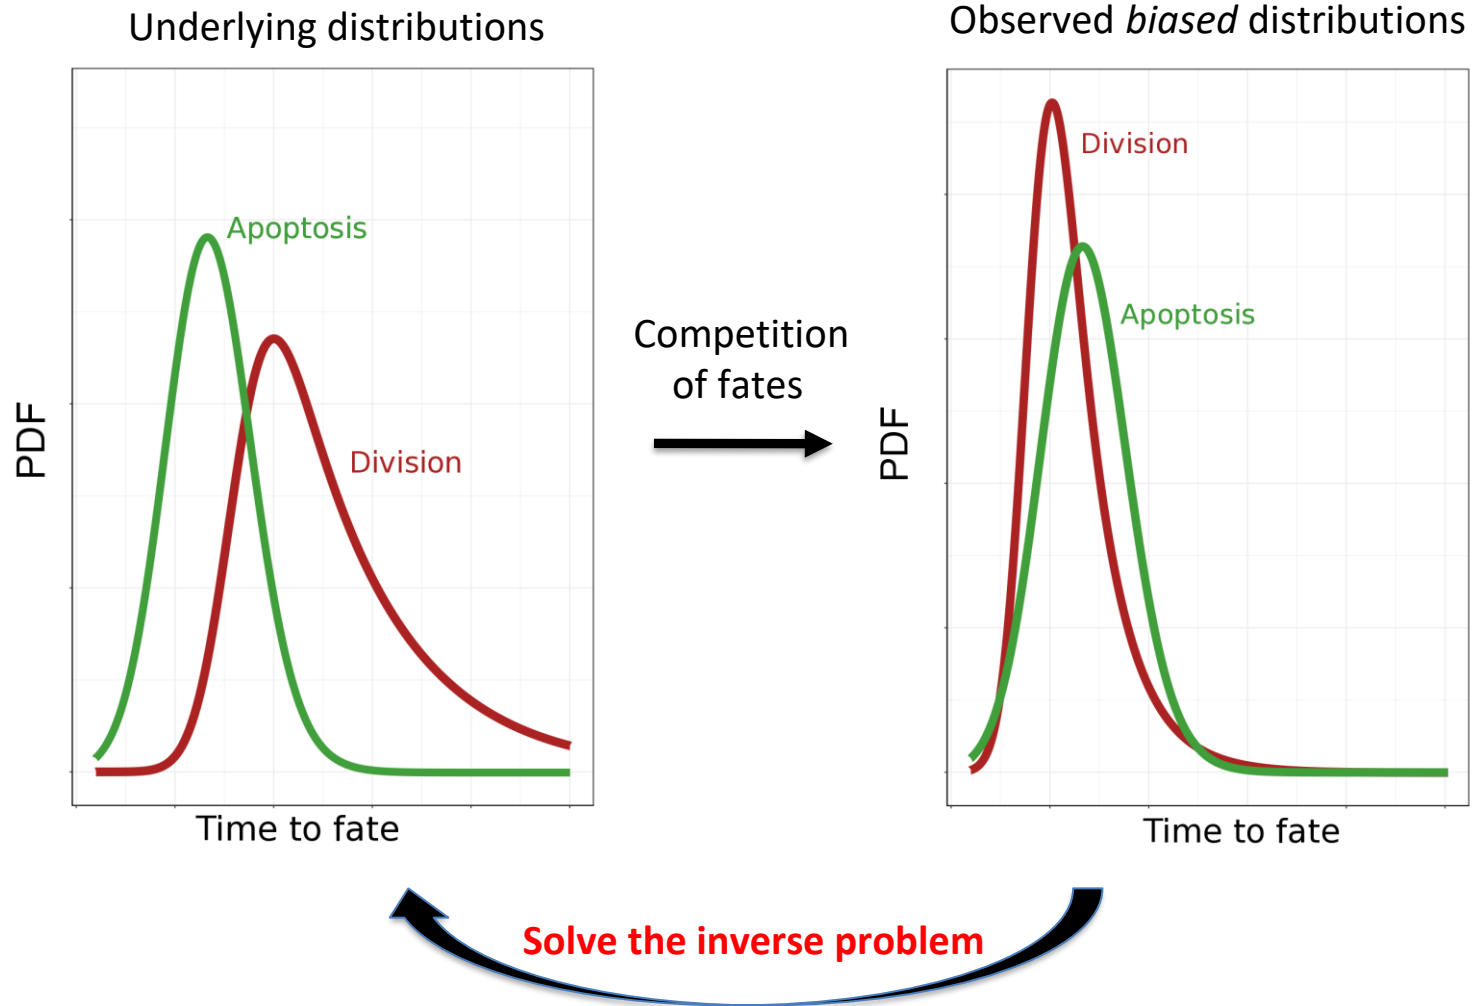

Coupling to ultradian rhythms *cannot* explain correlations

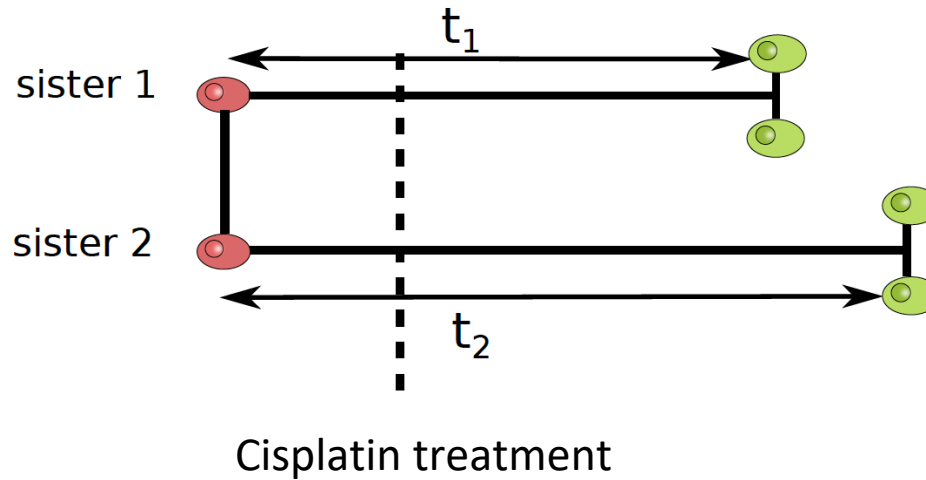

Cisplatin increases the heterogeneity of cell division times

Stochastic competition of fates biases observed distributions

An algorithm to infer hidden heterogeneity induced by cisplatin

$$S(t) = \Pr(T > t) = 1 - F(t) \quad (\text{Survival function})$$

$h(t)$ = Hazard function

$$f_i(t_1^i, t_2^i; \boldsymbol{\theta}) = c_z(1 - S^i(t_1^i), 1 - S^i(t_2^i)) S^i(t_1^i) h(t_1^i; \boldsymbol{\theta}) S^i(t_2^i) h(t_2^i; \boldsymbol{\theta})$$

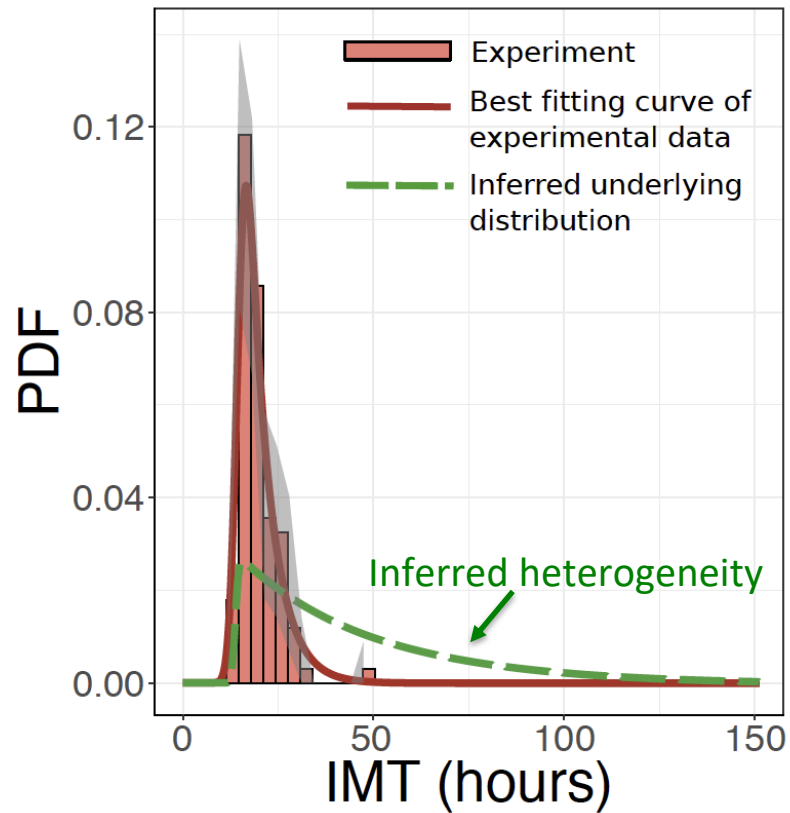

Joint density of
the two sisters

Copula accounts for
sister correlations

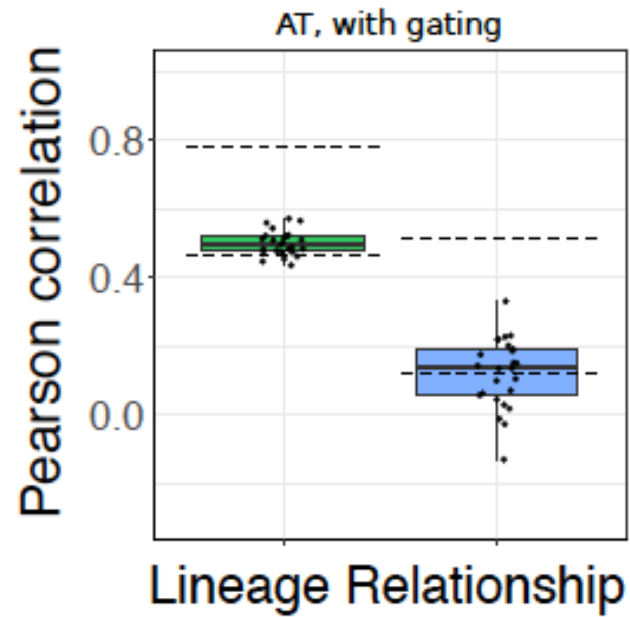

Marginal density
of sister 1

Marginal density
of sister 2

Hidden heterogeneity in cell division times after cisplatin administration

Correlations after cisplatin treatment can also be explained by the circadian gating model

Summary

- Current understanding of cell fate control based on stochastic protein production/degradation cannot explain the cousin-mother inequality.
- A mathematical model based on hazard functions provides a general framework to describe gating of cell division and death.
- Coupling of circadian, not ultradian oscillations to cell division explains the cousin-mother inequality
- A computational algorithm to infer the true underlying distributions of cell division and death times in the presence of competing fates.
