The storage effect

Peter Chesson (1985, 1994, ..., 2019)

What does storage mean?

The gain in reproduction during favorable periods is stored in some way (e.g., through adult longevity in species with overlapping generations, or dormant seeds in annual plants) so that the population can survive the losses it suffers during unfavorable periods.

Storage effect

Species experience little or no inter-specific interactions (e.g., competition, predation) when rare, and experience mostly self-limitation (e.g., intra-specific competition) when abundant.

Components of the storage effect

1. Species-specific responses to environmental variation
2. Negative or no correlation between favorability of the environment and strength of inter-specific competition
3. Buffered population growth

1. Species specific responses to environmental variation

Environmental variation mostly abiotic (e.g., temperature, rainfall)

1. Species-specific responses to environmental variation

The environment that maximizes fitness is not the same for all species (e.g., colder vs. warmer periods of the year, serpentine vs. non-serpentine soil)

Species differ in the way they respond to abiotic environmental variation (e.g., temperature, rainfall)

e.g., some do better at warmer temperatures, others do better at cooler temperatures

Species-specific responses ==> **an environment favorable to one species is unfavorable to its competitors**

==> mostly encounter conspecifics

==> strong intra-specific competition and little or no inter-specific competition

Components of the storage effect

1. Species-specific responses to environmental variation ✓

2. Correlation between environmental favorability and strength of competition

3. Buffered population growth

An environment favorable to one species is unfavorable to its competitors

==> little or no inter-specific competition during unfavorable periods for competitor

==> strong intra-specific competition during favorable periods for focal species

2. Correlation between environmental favorability and strength of competition

Negative or zero correlation between favorability of the environment and strength of inter-specific competition

Components of the storage effect

1. Species-specific responses to environmental variation ✓
2. Correlation between environmental favorability and strength of competition ✓
3. **Buffered population growth**

3. Buffered population growth

Species have a mechanism to survive unfavorable environments in space or time (e.g., dormancy, dispersal, high adult longevity)

Components of the storage effect

1. Species-specific responses to environmental variation
2. Zero or Negative correlation between favorability of the environment and strength of inter-specific competition
3. Buffered population growth

Spatial/temporal niche partitioning via
the storage effect

Storage effect

A mechanism for temporal niche partitioning framed in terms of species' responses to abiotic environmental variation

A hierarchy of mechanisms

Mechanism for temporal niche partitioning:

Storage effect

Mechanism of the **Storage effect**:

Interplay between environment variation and competition increases intra-specific interactions relative to inter-specific interactions

Mechanistic basis of the storage effect

Temperature as the axis of abiotic variation

Temperature as the axis of abiotic variation

1. Ubiquitous (diurnal, seasonal)
2. Direct (ectotherms) and indirect (endotherms) effects
3. Perturbations (climate warming)

Challenge

Non-linearities due to density dependence

Non-linearity in species' responses to abiotic (temperature) variation

Interplay between non-linearities

Community level: temporal niche partitioning

Species level: storage effect

Individual level: phenotypic traits

Goal

Predict outcomes of temporal niche partitioning via the storage effect based on how temperature variation affects the underlying life history and consumption traits

Characterizing temperature responses of phenotypic traits

Seasonal temperature variation

Mutual invasibility criteria in seasonally
varying environments

Mutual invasibility criteria

$$\frac{1}{\tau} \int_0^{\tau} \frac{1}{C_i(t)} \frac{dC_i(t)}{dt} dt > 0$$

$i=1, 2$

Time-averaged per capita growth rate when rare

Mutual invasibility criteria

$$\frac{1}{\tau} \int_0^\tau \frac{dC_i}{dt} \frac{1}{C_i} = \frac{1}{\tau} \int_0^\tau e_i a_i(T(t)) R_{C_j}(T(t)) - d_i(T(t)) dt > 0$$

$i, j = 1, 2, i \neq j$

(1)

$R_{C_j}(T(t))$: instantaneous resource availability set by the resident consumer in a seasonally varying environment (time-varying R^*)

When the consumers exhibit linear functional responses and temperature variation is predictable (i.e., mean temperature and the amplitude of seasonal fluctuations remain approximately constant over time), the instantaneous resource availability set by the resident consumer is given by:

$$R_{C_j}(T(t)) = \frac{d_j(T(t))}{e_j a_j(T(t))}.$$

Mutual invisibility criteria in seasonal environments

$$\frac{1}{\tau} \int_0^\tau \frac{dC_i}{dt} \frac{1}{C_i} = \frac{1}{\tau} \int_0^\tau e_i a_i(T(t)) \frac{d_j(T(t))}{e_j a_j(T(t))} - d_i(T(t)) dt > 0$$

$i, j = 1, 2, i \neq j$

Mutual invasibility criteria in seasonal environments

$$\frac{\int_0^{\tau} \frac{e_i a_i(T(t))}{e_j a_j(T(t))} d_j(T(t)) dt}{\int_0^{\tau} d_i(T(t)) dt} > 1.$$

Consumer i 's lifetime reproductive success in a seasonal environment

After separating the temperature-independent components and doing some algebra, we can derive the **sufficient** condition for mutual invasibility.

Sufficient condition for mutual invasibility

$$\frac{\int_0^\tau d'_2(T(t))dt}{\int_0^\tau a'_2(T(t)) \frac{d'_1(T(t))}{a'_1(T(t))} dt} < \frac{R_{1T_{\text{opt}}}}{R_{2T_{\text{opt}}}} < \frac{\int_0^\tau a'_1(T(t)) \frac{d'_2(T(t))}{a'_2(T(t))} dt}{\int_0^\tau d'_1(T(t))dt} \quad (1)$$

where

$$R_{iT_{\text{opt}}} = \frac{d_{iT_R}}{e_i a_{iT_{\text{opt}}}} \quad i, j = 1, 2, i \neq j, \text{ and,}$$

$d'_i(T(t))$ and $a'_i(T(t))$ are the temperature-dependent mortality and consumption rates.

Necessary condition for mutual invasibility

$$\frac{\int_0^\tau d_2(T(t))dt}{\int_0^\tau a_2(T(t)) \frac{d_1(T(t))}{a_1(T(t))} dt} < \frac{\int_0^\tau a_1(T(t)) \frac{d_2(T(t))}{a_2(T(t))} dt}{\int_0^\tau d_1(T(t))dt} \quad (1)$$

Note: hats have been dropped for convenience.

Necessary condition for mutual invasibility

$$\left(\frac{\int_0^\tau d_1(T(t))dt}{\int_0^\tau a_2(T(t)) \frac{d_1(T(t))}{a_1(T(t))} dt} \right) \left(\frac{\int_0^\tau d_2(T(t))dt}{\int_0^\tau a_1(T(t)) \frac{d_2(T(t))}{a_2(T(t))} dt} \right) < 1$$

Criteria for coexistence in seasonal environments

Necessary and sufficient \implies species limit themselves more than they do others \implies **stable coexistence**

Necessary only \implies one species excludes the other \implies **competitive dominance**

Neither necessary nor sufficient \implies outcome depends on initial conditions \implies **priority effects**

The necessary condition from the consumer-resource model:

$$\left(\frac{\int_0^\tau d_1(T(t))dt}{\int_0^\tau a_2(T(t)) \frac{d_1(T(t))}{a_1(T(t))} dt} \right) \left(\frac{\int_0^\tau d_2(T(t))dt}{\int_0^\tau a_1(T(t)) \frac{d_2(T(t))}{a_2(T(t))} dt} \right) < 1 \quad (1)$$

is equivalent to the necessary condition for mutual invasibility in the Lotka-Volterra framework:

$$\left(\frac{\alpha_{21}}{\alpha_{11}} \right) \left(\frac{\alpha_{12}}{\alpha_{22}} \right) < 1 \quad (2)$$

with

$$\alpha_{ii} = \frac{1}{\int_0^{\tau} d_i(T(t)) dt}$$

Intra-specific
competition coefficient

$$\alpha_{ji} = \frac{1}{\int_0^{\tau} a_j(T(t)) \frac{a_i(T(t))}{d_i(T(t))} dt}$$

Inter-specific
competition coefficient

$$i, j = 1, 2, i \neq j$$

$$\alpha_{ii} = \frac{1}{\int_0^{\tau} d_i(T(t)) dt}$$

Mechanistic derivation of competition coefficients based on species' consumption and mortality rates

$$\alpha_{ji} = \frac{1}{\int_0^{\tau} a_j(T(t)) \frac{a_i(T(t))}{d_i(T(t))} dt}$$

$$i, j = 1, 2, i \neq j$$

Intra-specific competition

$$\alpha_{ii} = \frac{1}{\frac{1}{\tau} \int_0^{\tau} d_i(T(t)) dt}$$

Intra-specific competition coefficient

Cold-adapted species experience stronger self-limitation than their warm-adapted competitors

Cold-adapted species deplete resource to lower levels (have lower R^*) than do their warm-adapted competitors

Differential adaptation to seasonal environments (response breadth)

Thermal specialist
 Lower average mortality
 Stronger self-limitation

Thermal generalist
 Higher average mortality
 Weaker self-limitation

Thermal specialists experience stronger self-limitation than thermal generalists

Thermal specialist
Lower resource availability
(Lower R^*)

Thermal generalist
Higher resource availability
(Higher R^*)

Thermal specialists depress resources to lower levels than thermal generalists

Differential adaptation to seasonal environments (response breadth)

Thermal specialists limit themselves more than their generalist competitors

Thermal specialists deplete resource to lower levels (have lower R^*) than do their generalist competitors

Mechanistic basis of storage effect in thermally variable environments

Species that exert **strong inter-specific competition** (e.g., cold-adapted species, thermal specialists) are **more self-limited** than those that exert only weak inter-specific competition (e.g., warm-adapted species and thermal generalists)

Developing testable predictions

Scaling temperature response parameters
in terms of seasonal temperature
regime

Empirical observations

1. Difference between thermal optimum and mean habitat temperature increases with increasing latitude

Tropical

Temperate

Temperature (K)

Empirical observations

2. Response breadth increases with increasing latitude (adaptation to larger seasonal fluctuations)

Tropical

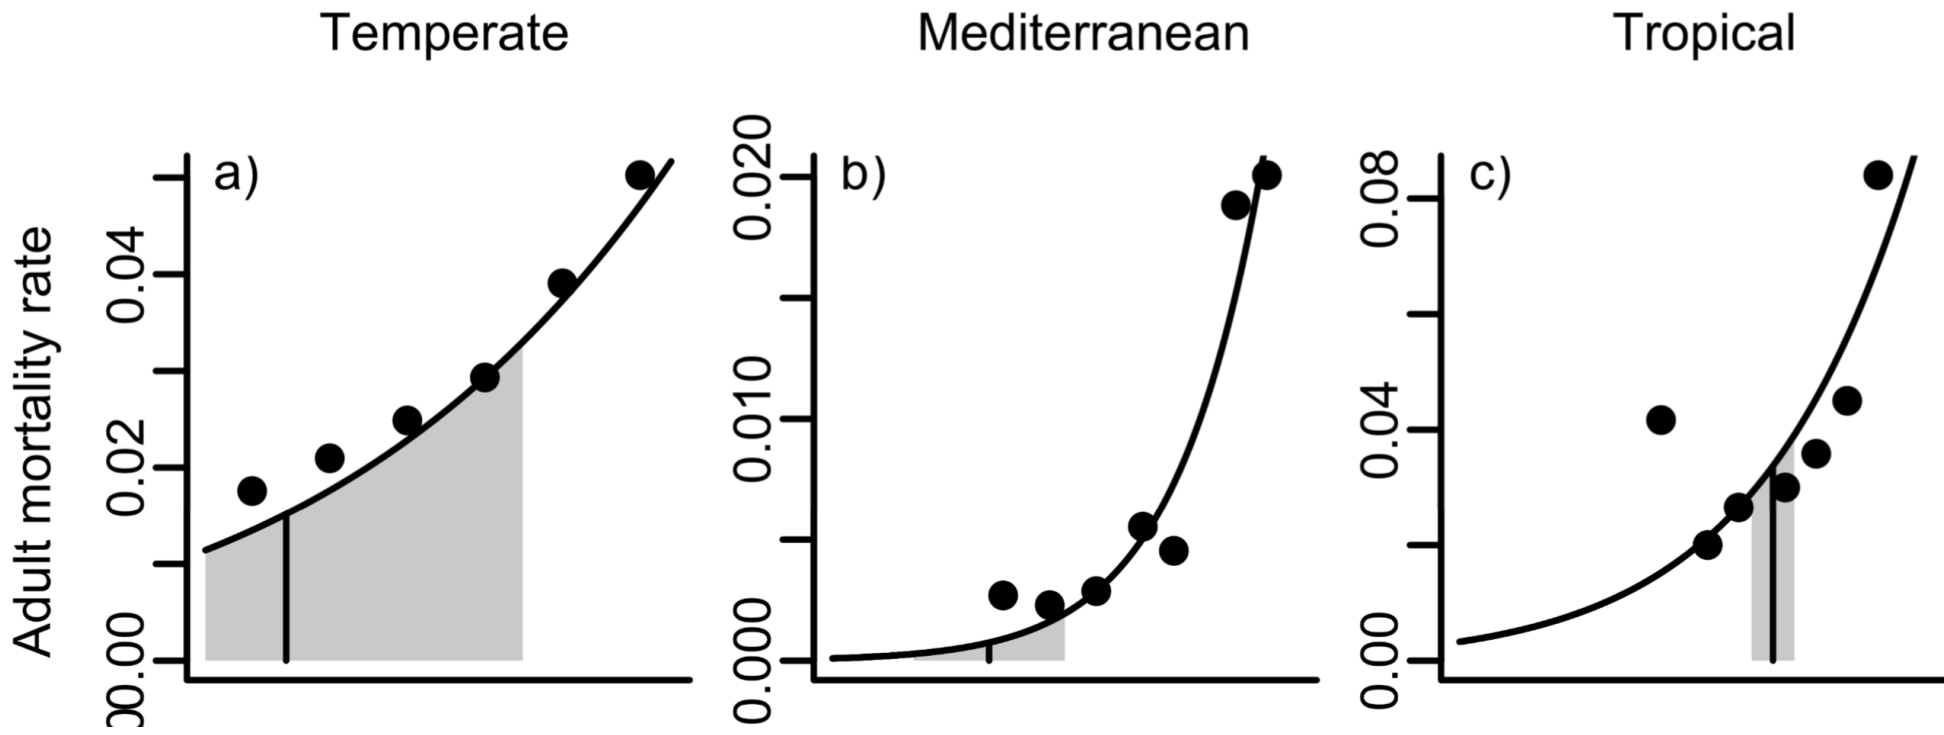

Temperate

Empirical observations

3. Species differ in their temperature sensitivity of mortality

Scaling of thermal optima

Let M_T denote the mean habitat temperature and A_T , the amplitude of seasonal fluctuations.

Consider Consumer 1 to be the resident species and Consumer 2 to be the invader.

Resident consumer's consumption rate: $T_{\text{opt}_{a_1}} = M_T + m$ where m is the deviation of the consumption optimum from mean habitat temperature.

Invader's consumption rate: $T_{\text{opt}_{a_2}} = T_{\text{opt}_{a_1}} + x$ where x is the deviation of invader's consumption optimum from that of resident.

Scaling of response breadth

Let s_{a_1} be the resident consumer's consumption response breadth.

Then $v = \frac{s_{a_2}}{s_{a_1}}$

where v is the ratio of invader's and resident's consumption response breadths

Scaling of temperature sensitivity of mortality

Let A_{d_1} be the resident consumer's Arrhenius constant for increase in mortality with temperature.

Then $p = \frac{A_{d_2}}{A_{d_1}}$

where p is the ratio of invader's and resident's temperature sensitivities of mortality.

By incorporating these scaling relationships into the mutual invisibility criteria

$$\left(\frac{\int_0^\tau d_1(T(t))dt}{\int_0^\tau a_2(T(t)) \frac{d_1(T(t))}{a_1(T(t))} dt} \right) \left(\frac{\int_0^\tau d_2(T(t))dt}{\int_0^\tau a_1(T(t)) \frac{d_2(T(t))}{a_2(T(t))} dt} \right) < 1 \quad (1)$$

and simplifying,

The necessary condition for mutual invasibility is given by:

$$\left(\frac{\int_0^\tau e^{-\frac{A_{d1}}{M_T - A_T S(t)}} dt}{\int_0^\tau e^{-AS(t)(S(t)+2n) - DS(t) - \frac{A_{d1}}{M_T - A_T S(t)}} dt} \right) \left(\frac{\int_0^\tau e^{-\frac{pA_{d1}}{M_T - A_T S(t)}} dt}{\int_0^\tau e^{AS(t)(S(t)+2n) + DS(t) - \frac{pA_{d1}}{M_T - A_T S(t)}} dt} \right) < 1$$

where $A = \frac{1-v^2}{2m^2v^2}$, $B_1 = \frac{A_{d1}A_T}{M_T+nA_T}$, $B_2 = \frac{A_{d1}A_T}{M_T+(n+x)A_T}$, $C = \frac{x}{m^2}$, $D = \frac{C}{v^2}$

Temperature sensitivity of mortality (p)

Insights

Density-independent mortality, which drives intra-specific competition (self-limitation), is crucial to coexistence in thermally variable environments.

Trait-based model provides mechanism for species-specific responses to temperature variation (temperature sensitivity of mortality p).

Predictions

1. Mutual invasibility possible if cold-adapted species (lower thermal optimum) experiences greater temperature sensitivity of mortality (steeper mortality curve).

Cold-adapted species

Steeper mortality curve,
Lower attack rate at higher temperatures

Warm-adapted species

Shallower mortality curve
Higher attack rate at higher temperatures

Cold-adapted species

1. Steeper mortality curve means lower mortality at lower temperatures and stronger self-limitation during favorable (colder) periods of the year.

Cold-adapted species

2. Steeper mortality curve also means higher mortality at high temperatures.

This, combined with its lower attack rate at higher temperatures increases the cold-adapted species' R^* , leading to **weaker competition** on the warm-adapted species when the **thermal environment is favorable to the warm-adapted species**.

Cold-adapted species

Lower attack rate optimum and greater temperature sensitivity of mortality ==> cold-adapted species limits itself more than it does its warm-adapted competitor.

Warm-adapted species

1. Shallower mortality curve means lower mortality at higher temperatures and stronger self-limitation during favorable (warmer) periods of the year.

Warm-adapted species

Shallower mortality curve also means higher mortality at lower temperatures. This, combined with its lower attack rate at lower temperatures increases the warm-adapted species' R^* , leading to **weak competition on the cold-adapted species** when the thermal environment is favorable to the cold-adapted species.

Warm-adapted species

Higher attack rate optimum and lower temperature sensitivity of mortality ==> warm-adapted species limits itself more than it does its cold-adapted competitor.

Thermal adaptation leads to negative covariance between the abiotic environment and the strength of interspecific competition

Criteria for coexistence in seasonal environments

Necessary and sufficient \implies species limit themselves more than they do others \implies **stable coexistence**

Necessary only \implies one species excludes the other \implies **competitive dominance**

Neither necessary nor sufficient \implies outcome depends on initial conditions \implies **priority effects**

Conditions for mutual invasibility

When **cold-adapted** species are **more** sensitive to temperature effects on density-independent mortality than warm-adapted species, *necessary condition for mutual invasibility criterion is always met*

Priority effects are not possible

Conditions for priority effects

When **cold-adapted** species are **less** sensitive to temperature effects on density-independent mortality than **warm-adapted** species, necessary condition for mutual invasibility is violated and **priority effects** arise.

Trait-based invasibility criteria

Predict conditions for coexistence, competitive dominance, and priority effects in thermally varying environments

Time (months)

Observed in the field

Time (months)

Exploitative competition in seasonally varying environments

Approach: derive mutual invasibility criteria in terms of mechanistic descriptions of trait responses to temperature

Key insights

1. Exponential nature of the mortality response causes self-limitation strength to decrease with increasing temperature

==> cold-adapted species and thermal specialists experience stronger intra-specific competition than warm-adapted species and thermal generalists.

2. Exponential nature of the mortality response translates into lower R^* and stronger inter-specific competition at temperatures below the attack rate optimum than above it.

Thermal adaptation is such that cold-adapted species and thermal specialists exert weaker competition warm-adapted species and thermal generalists when environment is favorable to warm-adapted species and thermal generalists and *vice versa*

Mechanistic basis on the storage effect in terms of temperature effects on life history and consumption traits

Species-specific responses arise from temperature effects on biochemical processes underlying species' traits

These trait effects translate into relative strengths of intra- vs. inter-specific competition at the population level.

Make testable predictions about population-level patterns of coexistence based solely on trait response data and completely independently on population-level information
